

bq21040 0.8A、单输入、单节锂离子和锂聚合物电池充电器

1 特性

- 充电中
 - 充电电压精度为 1%
 - 10% 充电电流精度
 - 低电池泄漏电流 ($1\mu\text{A}$)
 - 可通过外部电阻编程设定的充电电流最高可达 800mA
 - 4.2V 锂离子和锂聚合物充电器
- 保护
 - 30V 额定输入电压；具有 6.6V 输入过压保护
 - 输入电压动态电源管理
 - 125°C 热调节；150°C 热关断保护
 - OUT 短路保护和 ISET 短路检测
 - 通过负温度系数 (NTC) 实现过热感测保护
 - 10 小时固定安全定时器
- 系统
 - 状态指示 - 充电/完成
 - 采用小型小外形尺寸晶体管 (SOT)-23 封装

2 应用

- 电子销售点 (EPOS)
- 医疗内窥镜
- BLE 扬声器和耳机
- 低功耗手持器件

3 说明

bq21040 器件是一款面向空间受限类便携式应用的高度集成锂离子和锂聚合物线性电池充电器中运行。此器件可由一个 USB 端口或交流适配器供电运行。具有输入过压保护的高输入电压范围支持低成本、未稳压的适配器。

bq21040 具有一个可为电池充电的单电源输出。如果在 10 小时的安全定时器期间内平均系统负载无法让电池充满电，则可以使系统负载与电池并联。

电池充电经历以下三个阶段：调节，恒定电流和恒定电压。在所有充电阶段，内部控制环路都会监控 IC 结温，当其超过内部温度阈值时，它会减少充电电流。

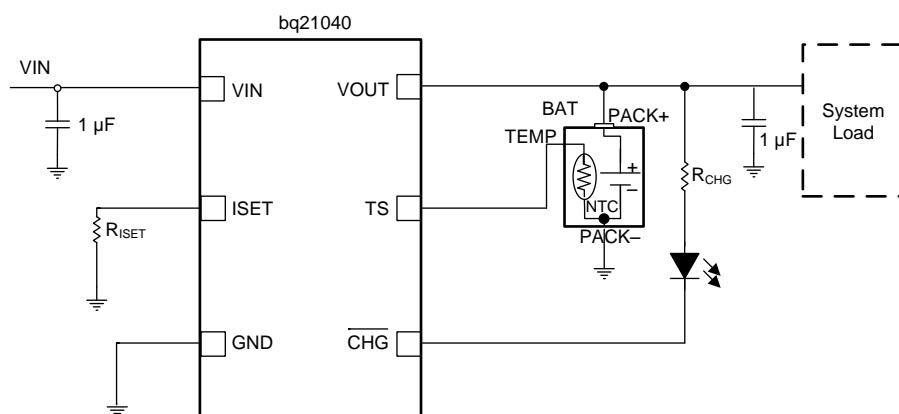

充电器功率级和充电电流感测功能均完全集成。该充电器具有高精度电流和电压调节环路功能、充电状态显示，和充电终止功能。预充电电流阈值和终止电流阈值分别固定为 20% 和 10%。快速充电电流值可通过一个外部电阻进行编程。

器件信息⁽¹⁾

器件型号	封装	封装尺寸（标称值）
bq21040	SOT-23 (6)	3.00mm x 1.75mm

Changes from Revision C (August 2017) to Revision D	Page
• Changed HBM From: ± 1000 To: ± 2000 in the <i>ESD Ratings</i>	4
• Changed CDM From: ± 250 To: ± 500 in the <i>ESD Ratings</i>	4

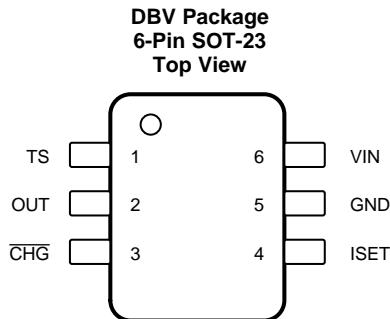

Changes from Revision B (May 2017) to Revision C	Page
• 已更改 简化原理图	1
• Changed 250 kΩ to 237 kΩ in TS pin description.....	3
• Changed R _{TS} max from 25.8 kΩ to 258 kΩ.....	4
• Changed Low temperature charging to Normal temperature charging in V _{TS-0C} Test Conditions	6
• Changed low temperature charging to normal temperature charging in V _{HYS-0C} Test Conditions	6
• Changed High temperature charging to Normal temperature charging in V _{TS-45C} Test Conditions	6
• Changed high temperature charging to normal temperature charging in V _{HYS-45C} Test Conditions	6
• 已删除 Load Regulation graph	7
• 已删除 Line Regulation graph	7
• 已更改 图 6	11
• 已删除 The bq21040 does not have a safety timer. in Timers	15
• 已更改 图 10	17

Changes from Revision A (April 2016) to Revision B	Page
• 更改了电气特性表中的最小值和最大值，更改了快速充电电流系数 KISET 的最小值和最大值	1
• 已添加 接收文档更新通知 部分	1

5 Device Comparison

PART NO.	$V_{O(REG)}$	V_{OVP}	TS	PACKAGE
bq21040	4.20 V	6.6 V	TS	3.00 mm × 1.75 mm × 1.45 mm SOT-23

6 Pin Configuration and Functions

Pin Functions

PIN		I/O	DESCRIPTION
NAME	NO.		
CHG	3	O	Low (FET on) indicates charging and Open Drain (FET off) indicates no Charging or Charge complete.
GND	5	—	Ground terminal
ISET	4	I	Programs the Fast-charge current setting. External resistor from ISET to VSS defines fast charge current value. Range is 10.8kΩ (50mA) to 675Ω (800mA).
OUT	2	O	Battery connection. System load may be connected. Expected range of bypass capacitors 1μF to 10μF.
TS	1	I	Temperature sense terminal connected to bq21040 -10k at 25°C NTC thermistor, in the battery pack. Floating T terminal or pulling High puts part in TTDM "Charger" Mode and disable TS monitoring, Timers and Termination. Pulling terminal Low disables the IC. If NTC sensing is not needed, connect this terminal to VSS through an external 10 kΩ resistor. A 237 kΩ from TS to ground will prevent IC entering TTDM mode when battery with thermistor is removed.
VIN	6	I	Input power, connected to external DC supply (AC adapter or USB port). Expected range of bypass capacitors 1μF to 10μF, connect from IN to V _{SS} .

7 Specifications

7.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)⁽¹⁾ ⁽²⁾

		MIN	MAX	UNIT
Input voltage	IN (with respect to VSS)	-0.3	30	V
	OUT (with respect to VSS)	-0.3	7	V
	PRE-TERM, ISET, ISET2, TS, /CHG (with respect to VSS)	-0.3	7	V
Input current	IN		1.25	A
Output current (continuous)	OUT		1.25	A
Output sink current	CHG		15	mA
Junction temperature, T_J		-40	150	°C
Storage temperature, T_{stg}		-65	150	°C

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- (2) All voltage values are with respect to the network ground terminal unless otherwise noted.

7.2 ESD Ratings

		VALUE	UNIT
V _(ESD)	Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	±2000
		Charged-device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	±500

(1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.

(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

7.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

	MIN	NOM	MAX	UNIT
V _{IN}	IN voltage range	3.5	28	V
	IN operating voltage range, restricted by VDPM and VOVP	4.45	6.45	V
I _{IN}	Input current, IN terminal		0.8	A
I _{OUT}	Current, OUT terminal		0.8	A
T _J	Junction temperature	0	125	°C
R _{ISET}	Fast-charge current programming resistor	0.675	10.8	kΩ
R _{TS}	10k NTC thermistor range without entering TTDM	1.66	258	kΩ

7.4 Thermal Information

THERMAL METRIC ⁽¹⁾		bq21040	UNIT
	DBV (SOT-23)		
	6 PINS		
R _{θJA}	Junction-to-ambient thermal resistance	130.8	°C/W
R _{θJC(top)}	Junction-to-case (top) thermal resistance	75.2	°C/W
R _{θJB}	Junction-to-board thermal resistance	45.5	°C/W
Ψ _{JT}	Junction-to-top characterization parameter	31.8	°C/W
Ψ _{JB}	Junction-to-board characterization parameter	45.5	°C/W
R _{θJC(bot)}	Junction-to-case (bottom) thermal resistance	n/a	°C/W

(1) For more information about traditional and new thermal metrics, see the [Semiconductor and IC Package Thermal Metrics](#) application report.

7.5 Electrical Characteristics

over operating free-air temperature range (unless otherwise noted)

PARAMETER	TEST CONDITIONS	MIN	TYP	MAX	UNIT

8 Detailed Description

8.1 Overview

The bq21040 is a highly integrated single cell Li-Ion and Li-Pol charger. The charger can be used to charge a battery, power a system or both. The charger has three phases of charging: Pre-charge to recover a fully discharged battery, fast-charge constant current to supply the buck charge safely and voltage regulation to safely reach full capacity. The charger is very flexible, allowing programming of the fast-charge current. This charger is designed to work with a USB connection or Adaptor (DC out). The charger also checks to see if a battery is present.

The charger also comes with a full set of safety features: Temperature Sensing Standard, Over-Voltage Protection, DPM-IN, Safety Timers, and ISET short protection. All of these features and more are described in detail below.

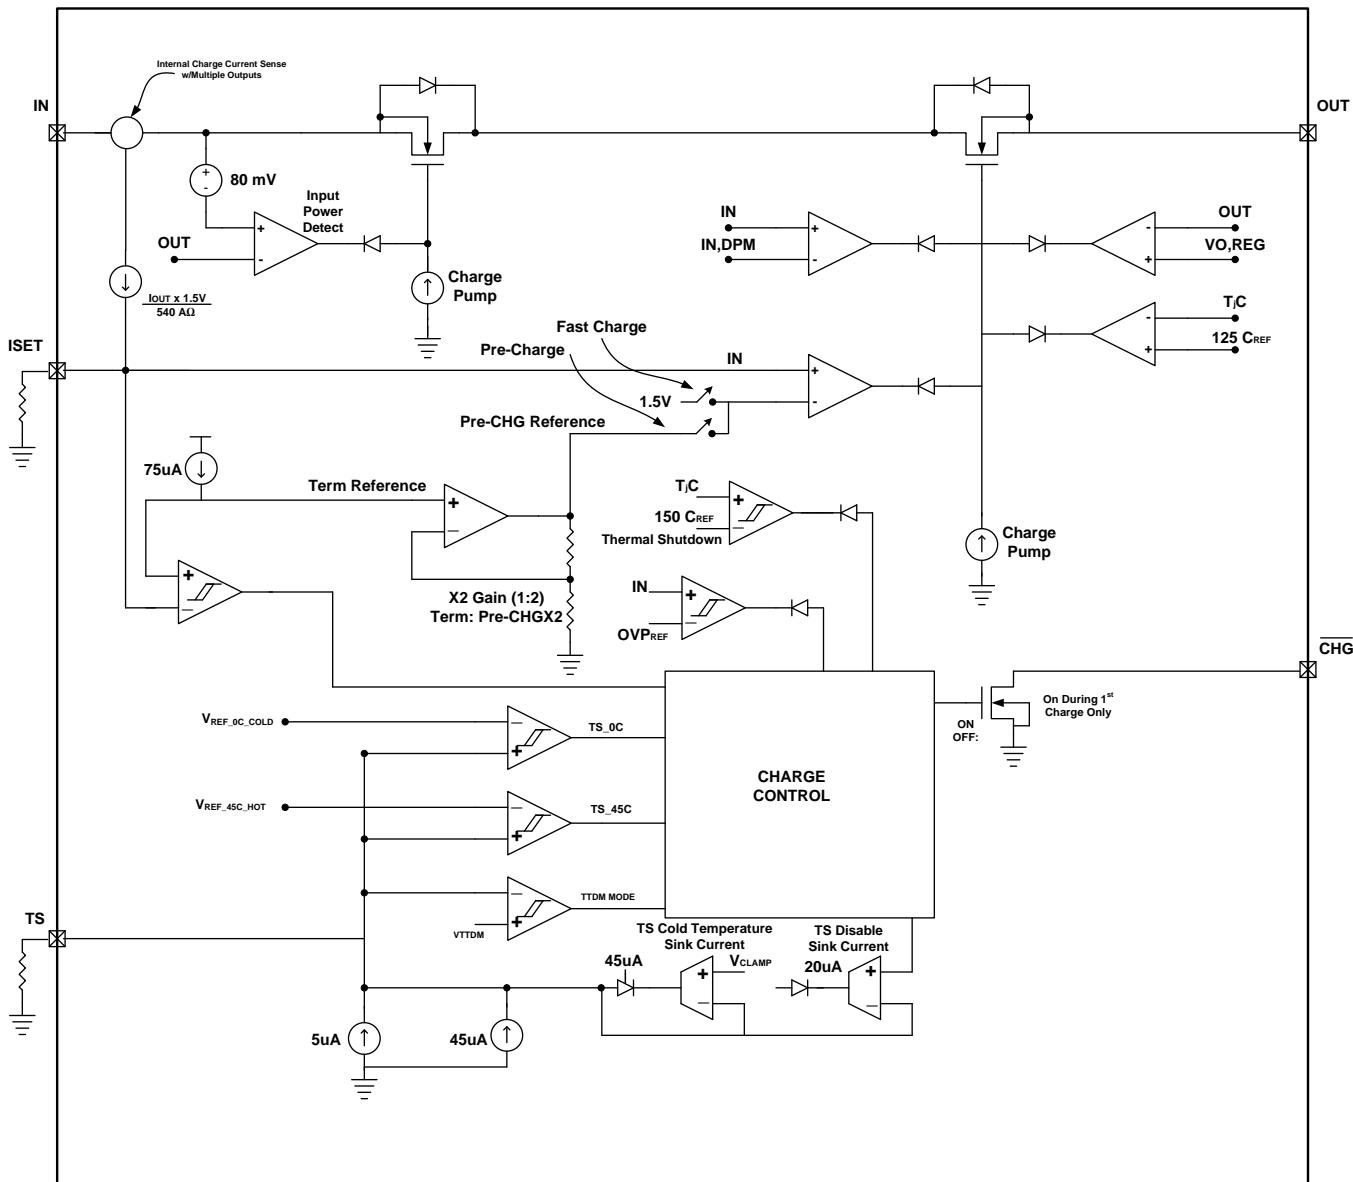

The charger is designed for a single power path from the input to the output to charge a single cell Li-Ion or Li-Pol battery pack. Upon application of a 5VDC power source the ISET and OUT short checks are performed to assure a proper charge cycle.

If the battery voltage is below the LOWV threshold, the battery is considered discharged and a preconditioning cycle begins. The amount of the current goes into the battery during this phase is called pre-charge current. It is fixed to 20% of the fast charge current.

Once the battery voltage has charged to the VLOWV threshold, fast charge is initiated and the fast charge current is applied. The fast charge constant current is programmed using the ISET terminal. The constant current provides the bulk of the charge. Power dissipation in the IC is greatest in fast charge with a lower battery voltage. If the IC reaches 125°C the IC enters thermal regulation, slows the timer clock by half and reduce the charge current as needed to keep the temperature from rising any further. [图 5](#) shows the charging profile with thermal regulation. Typically under normal operating conditions, the IC's junction temperature is less than 125°C and thermal regulation is not entered.

Once the cell has charged to the regulation voltage the voltage loop takes control and holds the battery at the regulation voltage until the current tapers to the termination threshold. The termination current is set to 10% of the fast charge current. The CHG terminal is low (LED on) during the first charge cycle only and turns off once the termination threshold is reached, regardless if termination, for charge current, is enabled or disabled.

8.2 Functional Block Diagram

8.3 Feature Description

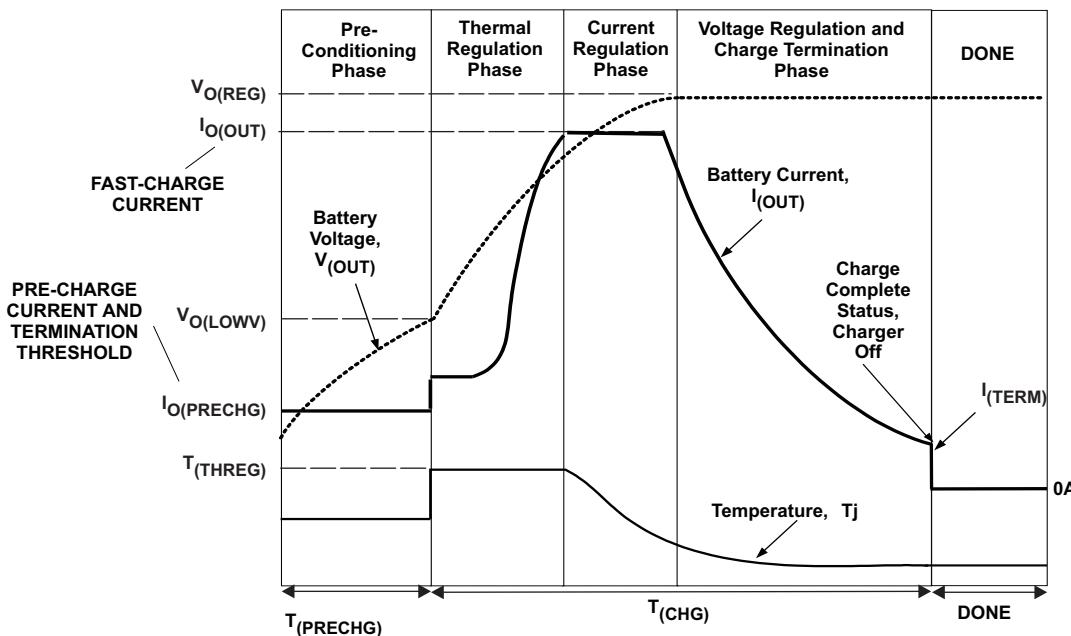

图 5. Charging Profile With Thermal Regulation

8.3.1 Power-Down or Undervoltage Lockout (UVLO)

The bq21040 is in power-down mode if the IN terminal voltage is less than UVLO. The part is considered “dead” and all the terminals are high impedance. Once the IN voltage rises above the UVLO threshold the IC will enter Sleep Mode or Active mode depending on the OUT terminal (battery) voltage.

8.3.2 Power-up

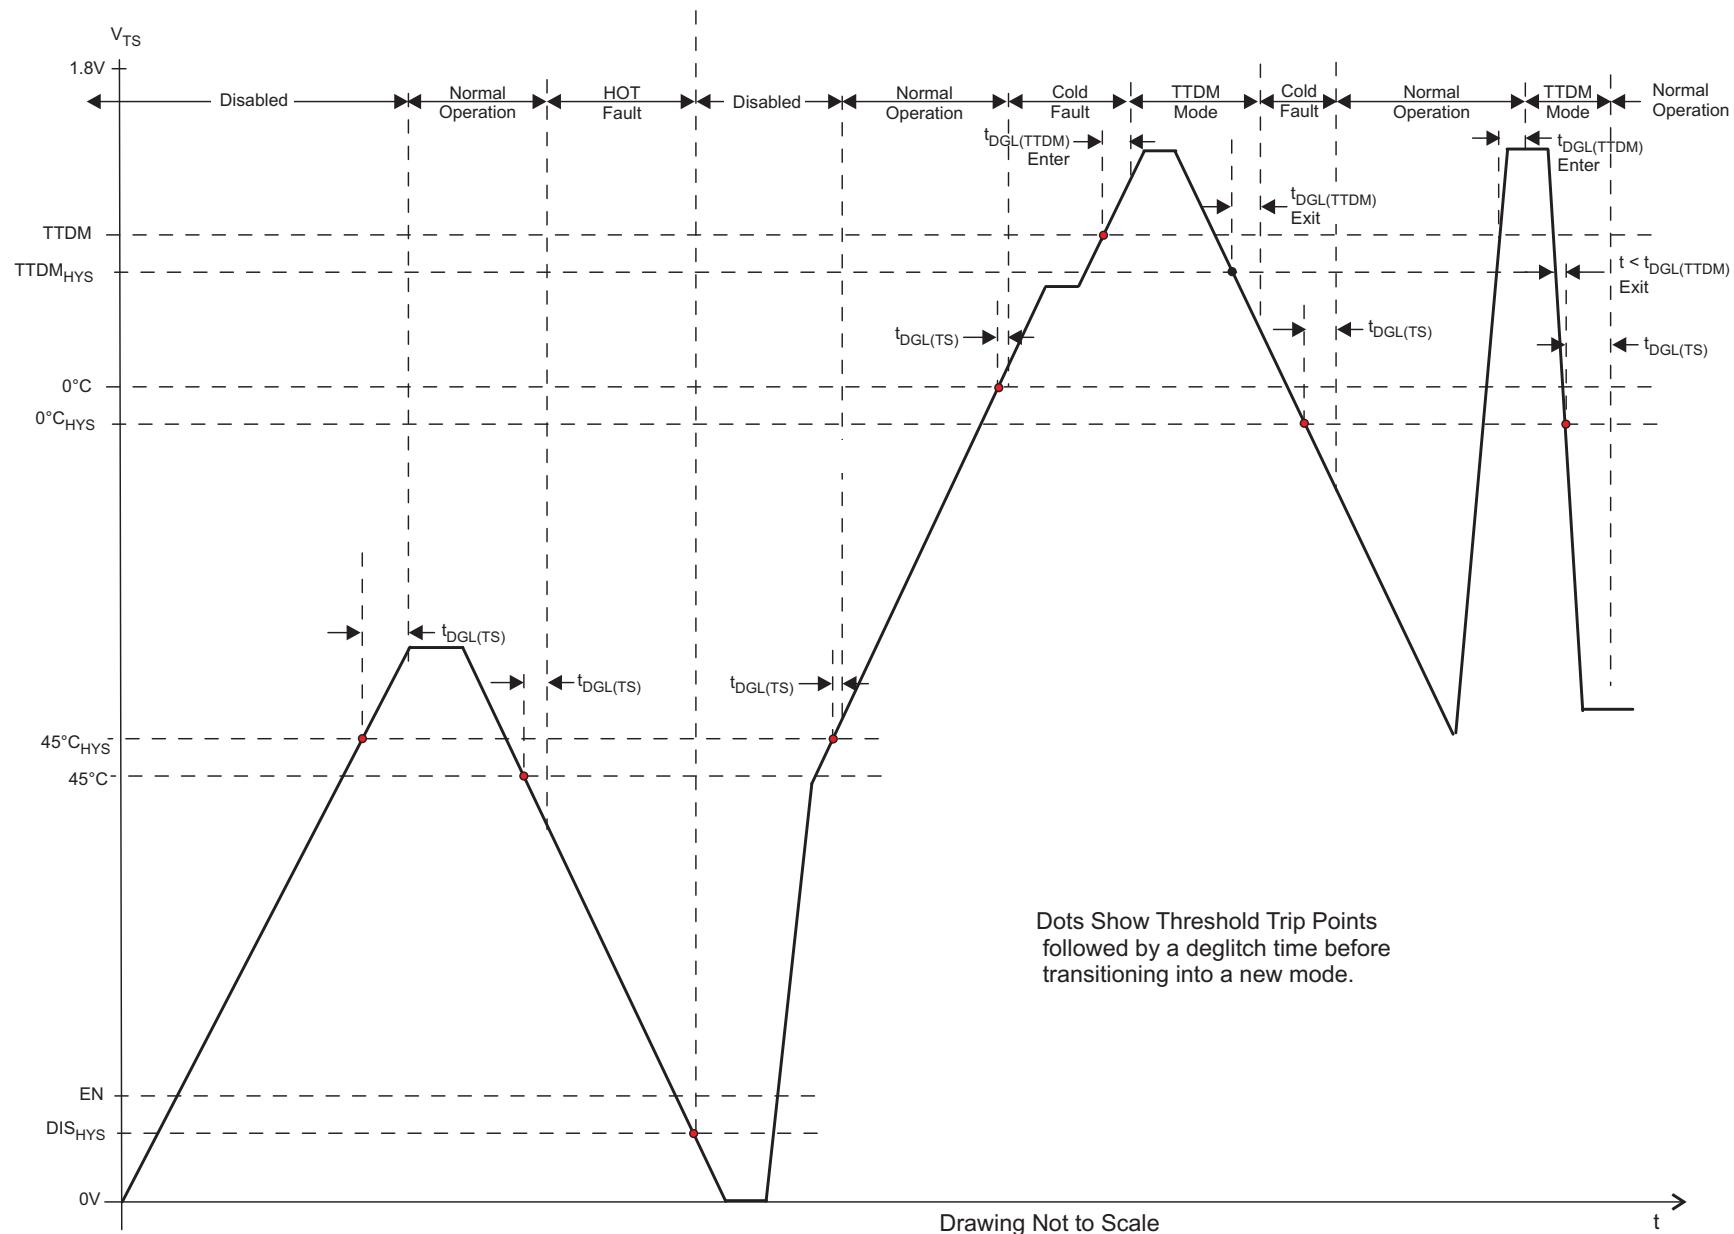

The IC is alive after the IN voltage ramps above UVLO (see sleep mode), resets all logic and timers, and starts to perform many of the continuous monitoring routines. Typically the input voltage quickly rises through the UVLO and sleep states where the IC declares power good, starts the qualification charge at 100mA starts the safety timer and enables the CHG terminal. See [图 6](#).

8.3.3 Sleep Mode

If the IN terminal voltage is between $V_{OUT}+V_{DT}$ and UVLO, the charge current is disabled, the safety timer counting stops (not reset) and the CHG terminal is high impedance. As the input voltage rises and the charger exits sleep mode, the safety timer continues to count, charge is enabled and the CHG terminal returns to its previous state. See [图 7](#).

8.3.4 New Charge Cycle

A new charge cycle is started when a good power source is applied, performing a chip disable/enable (TS terminal), exiting Termination and Timer Disable Mode (TTDM), detecting a battery insertion or the OUT voltage dropping below the VRCH threshold. The CHG terminal is active low only during the first charge cycle, therefore exiting TTDM or a dropping below VRCH will not turn on the CHG terminal FET, if the CHG terminal is already high impedance.

图 6. TS Battery Temperature Bias Threshold and Deglitch Timers

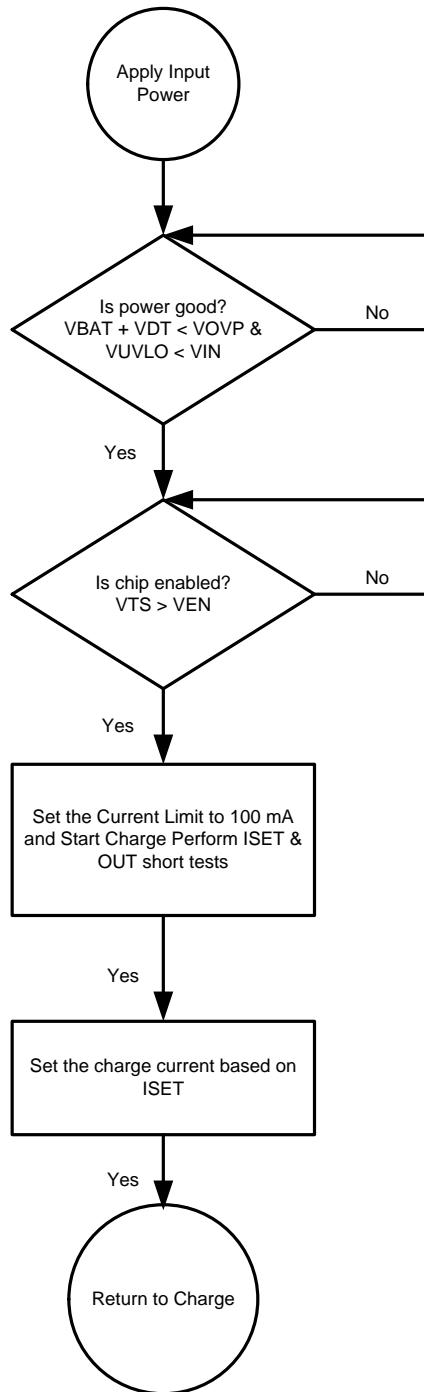

图 7. bq21040 Power-Up Flow Diagram

8.3.5 Overvoltage-Protection (OVP) – Continuously Monitored

If the input source applies an overvoltage, the pass FET, if previously on, turns off after a deglitch, $t_{BLK(OVP)}$. The timer ends and the CHG terminal goes to a high impedance state. After the overvoltage returns to a normal voltage, the timer continues, charge continues, and the CHG terminal goes low after a 25ms deglitch.

8.3.6 **CHG** Terminal Indication

The charge terminal has an internal open drain FET which is on (pulls down to V_{SS}) during the first charge only (independent of TTDM) and is turned off once the battery reaches voltage regulation and the charge current tapers to the termination threshold set by the PRE-TERM resistor. The bq21040 does not terminate charge, however, the **CHG** terminal will turn off once the battery current reaches 10% of the programmed charge current.

The charge terminal is high impedance in sleep mode and OVP and returns to its previous state once the condition is removed.

Cycling input power, pulling the TS terminal low and releasing or entering pre-charge mode causes the **CHG** terminal to go reset (go low if power is good and a discharged battery is attached) and is considered the start of a first charge.

8.4 Device Functional Modes

8.4.1 **CHG** LED Pull-up Source

For host monitoring, a pullup resistor is used between the STATUS terminal and the V_{CC} of the host and for a visual indication a resistor in series with an LED is connected between the STATUS terminal and a power source. If the CHG source is capable of exceeding 7 V, a 6.2-V Zener should be used to clamp the voltage. If the source is the OUT terminal, note that as the battery changes voltage, and the brightness of the LEDs vary.

表 1. Charging States and **CHG LED**

CHARGING STATE	CHG FET/LED
First charge after VIN applied	ON
Refresh charge	
OVP	OFF
SLEEP	
TEMP FAULT	ON for 1st Charge

8.4.2 IN-DPM (V_{IN} -DPM or IN-DPM)

The IN-DPM feature is used to detect an input source voltage that is folding back (voltage dropping), reaching its current limit due to excessive load. When the input voltage drops to the $V_{IN\text{-}DPM}$ threshold the internal pass FET starts to reduce the current until there is no further drop in voltage at the input. This would prevent a source with voltage less than $V_{IN\text{-}DPM}$ to power the out terminal. This works well with current limited adaptors and USB ports as long as the nominal voltage is above 4.3 V. This is an added safety feature that helps protect the source from excessive loads.

8.4.3 OUT

The Charger's OUT terminal provides current to the battery and to the system, if present. This IC can be used to charge the battery plus power the system, charge just the battery or just power the system (TTDM) assuming the loads do not exceed the available current. The OUT terminal is a current limited source and is inherently protected against shorts. If the system load ever exceeds the output programmed current threshold, the output will be discharged unless there is sufficient capacitance or a charged battery present to supplement the excessive load.

8.4.4 ISET

An external resistor is used to Program the Output Current (50 to 800 mA) and can be used as a current monitor.

$$R_{ISET} = K_{ISET} / I_{OUT}$$

where

- I_{OUT} is the desired fast charge current;
 - K_{ISET} is a gain factor found in the electrical specification
- (1)

For greater accuracy at lower currents, part of the sense FET is disabled to give better resolution. 图 1 shows the transition from low current to higher current. Going from higher currents to low currents, there is hysteresis and the transition occurs around 0.15 A.

The ISET resistor is short protected and will detect a resistance lower than $\pm 340\ \Omega$. The detection requires at least 80mA of output current. If a “short” is detected, then the IC will latch off and can only be reset by cycling the power. The OUT current is internally clamped to a maximum current between 1.05 A and 1.4 A and is independent of the ISET short detection circuitry, as shown in [图 8](#). Also, see [图 23](#) and [图 24](#).

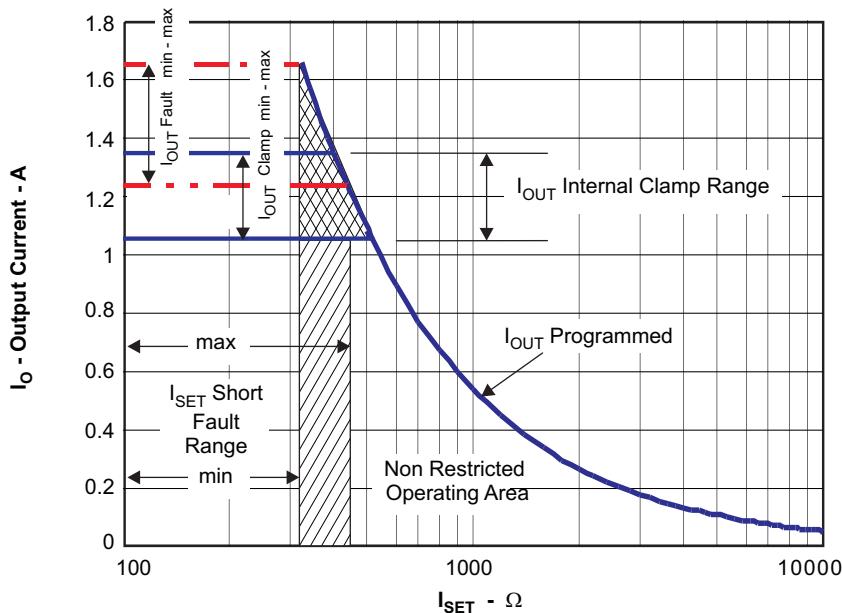

图 8. Programmed/Clamped Out Current

8.4.5 TS

The TS function is designed to follow the temperature sensing standard for Li-Ion and Li-Pol batteries. There are two thresholds, 45°C and 0°C. Normal operation occurs between 0°C and 45°C.

The TS feature is implemented using an internal 50 μ A current source to bias the thermistor (designed for use with a 10k NTC $\beta = 3370$ (SEMITEC 103AT-2 or Mitsubishi TH05-3H103F) connected from the TS terminal to V_{SS}). If this feature is not needed, a fixed 10k Ω can be placed between TS and V_{SS} to allow normal operation. This may be done if the host is monitoring the thermistor and then the host would determine when to pull the TS terminal low to disable charge.

The TS terminal has two additional features, when the TS terminal is pulled low or floated/driven high. A low disables charge (similar to a high on the BAT_EN feature) and a high puts the charger in TTDM.

Above 45°C or below 0°C the charge is disabled. Once the thermistor reaches $\pm 10^\circ\text{C}$ the TS current folds back to keep a cold thermistor (between -10°C and -50°C) from placing the IC in the TTDM mode. If the TS terminal is pulled low into disable mode, the current is reduced to $\pm 30\mu\text{A}$, see [图 6](#). Since the I_{TS} current is fixed along with the temperature thresholds, it is not possible to use thermistor values other than the 10k NTC (at 25°C).

8.4.6 Termination and Timer Disable Mode (TTDM) - TS Terminal High

The battery charger is in TTDM when the TS terminal goes high from removing the thermistor (removing battery pack/floating the TS terminal) or by pulling the TS terminal up to the TTDM threshold.

When entering TTDM, the 10 hour safety timer is held in reset and termination is disabled. A battery detect routine is run to see if the battery was removed or not. If the battery was removed then the CHG terminal will go to its high impedance state if not already there. If a battery is detected the CHG terminal does not change states until the current tapers to the termination threshold, where the CHG terminal goes to its high impedance state if not already there (the regulated output will remain on).

The charging profile does not change (still has pre-charge, fast-charge constant current and constant voltage modes). This implies the battery is still charged safely and the current is allowed to taper to zero.

When coming out of TTDM, the battery detect routine is run and if a battery is detected, then a new charge cycle begins and the CHG LED turns on.

If TTDM is not desired upon removing the battery with the thermistor, one can add a 237k resistor between TS and V_{SS} to disable TTDM. This keeps the current source from driving the TS terminal into TTDM. This creates $\pm 0.1^\circ\text{C}$ error at hot and a $\pm 3^\circ\text{C}$ error at cold.

8.4.7 Timers

The pre-charge timer is set to 30 minutes. The pre-charge current, can be programmed to off-set any system load, making sure that the 30 minutes is adequate.

The fast charge timer is fixed at 10 hours and can be increased real time by going into thermal regulation, IN-DPM or if in USB current limit. The timer clock slows by a factor of 2, resulting in a clock than counts half as fast when in these modes. If either the 30 minute or ten hour timer times out, the charging is terminated and the CHG terminal goes high impedance if not already in that state. The fast charge timer is reset by disabling the IC, cycling power or going into and out of TTDM.

8.4.8 Termination

Once the OUT terminal goes above VRCH, (reaches voltage regulation) and the current tapers down to the termination threshold (10% of the fast charge current), the CHG terminal goes high impedance and a battery detect route is run to determine if the battery was removed or the battery is full. If the battery is present, the charge current will terminate. If the battery was removed along with the thermistor, then the TS terminal is driven high and the charge enters TTDM. If the battery was removed and the TS terminal is held in the active region, then the battery detect routine will continue until a battery is inserted.

8.4.9 Battery Detect Routine

The battery detect routine should check for a missing battery while keeping the OUT terminal at a useable voltage. Whenever the battery is missing the CHG terminal should be high impedance.

The battery detect routine is run when entering and exiting TTDM to verify if battery is present, or run all the time if battery is missing and not in TTDM. On power-up, if battery voltage is greater than V_{RCH} threshold, a battery detect routine is run to determine if a battery is present.

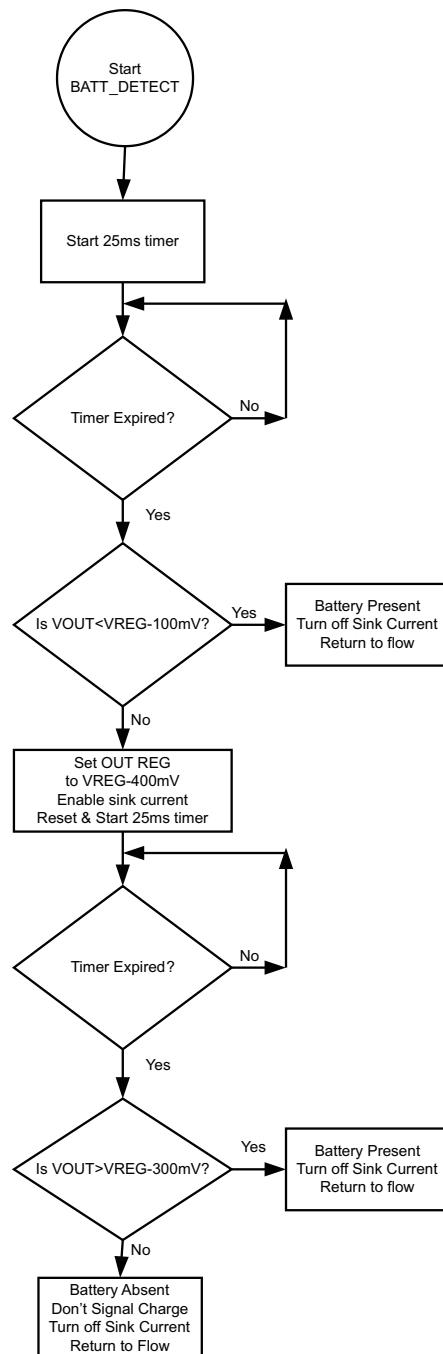

The battery detect routine is disabled while the IC is in TTDM, or has a TS fault. See [图 9](#) for the Battery Detect Flow Diagram.

8.4.10 Refresh Threshold

After termination, if the OUT terminal voltage drops to V_{RCH} (100mV below regulation) then a new charge is initiated, but the CHG terminal remains at a high impedance (off).

8.4.11 Starting a Charge on a Full Battery

The termination threshold is raised by $\pm 14\%$, for the first minute of a charge cycle so if a full battery is removed and reinserted or a new charge cycle is initiated, that the new charge terminates (less than 1 minute). Batteries that have relaxed many hours may take several minutes to taper to the termination threshold and terminate charge.

9 Application and Implementation

注

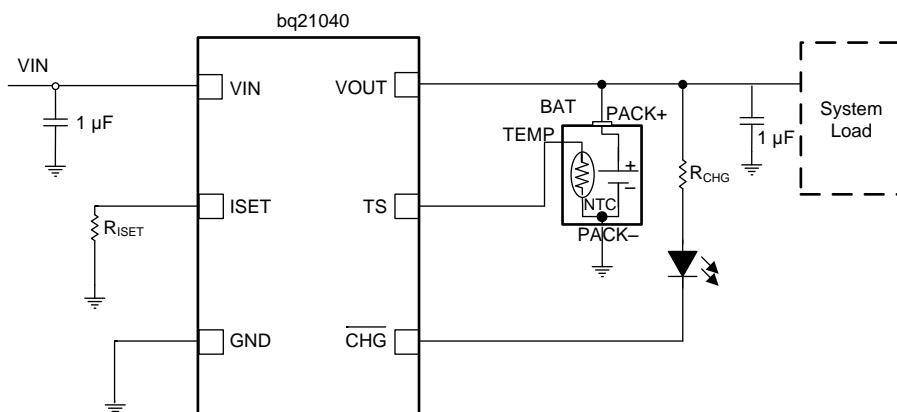

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

9.1 Application Information

The bq21040 device is a highly integrated Li-Ion and Li-Po linear charger device targeted at space-limited portable applications. The device operates from either a USB port or AC adapter. The high input voltage range with input overvoltage protection supports low-cost unregulated adapters. This device has a single power output that charges the battery. A system load can be placed in parallel with the battery as long as the average system load does not keep the battery from charging fully during the 10 hour safety timer.

9.2 Typical Application

$$I_{OUT_FAST_CHG} = 540\text{mA}; I_{OUT_PRE_CHG} = 108\text{mA}; I_{OUT_TERM} = 54\text{mA}$$

Copyright © 2016, Texas Instruments Incorporated

图 10. Typical Application Circuit

9.2.1 Design Requirements

- Supply voltage = 5 V
- Fast charge current: $I_{OUT-FC} = 540 \text{ mA}$; ISET-terminal 2
- Termination Current Threshold: $\%I_{OUT-FC} = 10\%$ of Fast Charge or about 54mA
- Pre-Charge Current by default is twice the termination Current or about 108mA
- TS – Battery Temperature Sense = 10k NTC (103AT)

Typical Application (接下页)

9.2.2 Detailed Design Procedure

9.2.2.1 Calculations

9.2.2.1.1 Program the Fast Charge Current, ISET:

$$R_{ISET} = [K_{(ISET)} / I_{(OUT)}] \quad (2)$$

From the *Electrical Characteristics* table:

- $K_{(SET)} = 540A\Omega$
- $R_{ISET} = [540A\Omega / 0.54A] = 1.0 k\Omega$

Selecting the closest standard value, use a 1.0 kΩ resistor between ISET (terminal 16) and Vss.

9.2.2.1.2 Pre-Charge and Termination Current Thresholds, ITERM, and PRE-CHG

$$TERM = I_{(OUT)} \times 10\% I_{OUT-FC} \quad (3)$$

$$TERM = 540mA \times 10\% = 54mA \quad (4)$$

One can calculate the pre-charge current by using 20% of the fast charge current (factor of 2 difference).

$$PRE\text{-Charge} = I_{(OUT)} \times 20\% I_{OUT-FC} \quad (5)$$

$$PRE\text{-Charge} = 540mA \times 20\% = 108mA \quad (6)$$

9.2.2.1.3 TS Function

Use a 10k NTC thermistor in the battery pack (103AT).

To Disable the temp sense function, use a fixed 10k resistor between the TS (terminal 1) and Vss.

9.2.2.1.4 CHG

LED Status: connect a 1.5kΩ resistor in series with a LED between the OUT terminal and the CHG terminal.

Processor Monitoring: Connect a pull-up resistor between the processor's power rail and the CHG terminal.

9.2.2.2 Selecting In and Out Terminal Capacitors

In most applications, all that is needed is a high-frequency decoupling capacitor (ceramic) on the power terminal, input and output terminals. Using the values shown on the application diagram, is recommended. After evaluation of these voltage signals with real system operational conditions, one can determine if capacitance values can be adjusted toward the minimum recommended values (DC load application) or higher values for fast high amplitude pulsed load applications. Note if designed for high input voltage sources (bad adaptors or wrong adaptors), the capacitor needs to be rated appropriately. Ceramic capacitors are tested to 2x their rated values so a 16V capacitor may be adequate for a 30V transient (verify tested rating with capacitor manufacturer).

10 Power Supply Recommendations

The devices are designed to operate from an input voltage supply range between 3.5 V and 28 V and current capability of at least the maximum designed charge current. This input supply should be well regulated. If located more than a few inches from the bq21040 IN and GND terminals, a larger capacitor is recommended.

11 Layout

11.1 Layout Guidelines

To obtain optimal performance, the decoupling capacitor from IN to GND (thermal pad) and the output filter capacitors from OUT to GND (thermal pad) should be placed as close as possible to the bq21040, with short trace runs to both IN, OUT, and GND (thermal pad).

- All low-current GND connections should be kept separate from the high-current charge or discharge paths from the battery. Use a single-point ground technique incorporating both the small signal ground path and the power ground path.
- The high current charge paths into IN terminal and from the OUT terminal must be sized appropriately for the maximum charge current in order to avoid voltage drops in these traces
- The bq21040 is packaged in a thermally-enhanced MLP package. The package includes a thermal pad to provide an effective thermal contact between the IC and the printed circuit board (PCB); this thermal pad is also the main ground connection for the device. Connect the thermal pad to the PCB ground connection. It is best to use multiple 10mil vias in the power pad of the IC and close enough to conduct the heat to the bottom ground plane. The bottom ground place should avoid traces that “cut off” the thermal path. The thinner the PCB the less temperature rise. The EVM PCB has a thickness of 0.031 inches and uses 2 oz. (2.8mil thick) copper on top and bottom, and is a good example of optimal thermal performance.

11.2 Layout Example

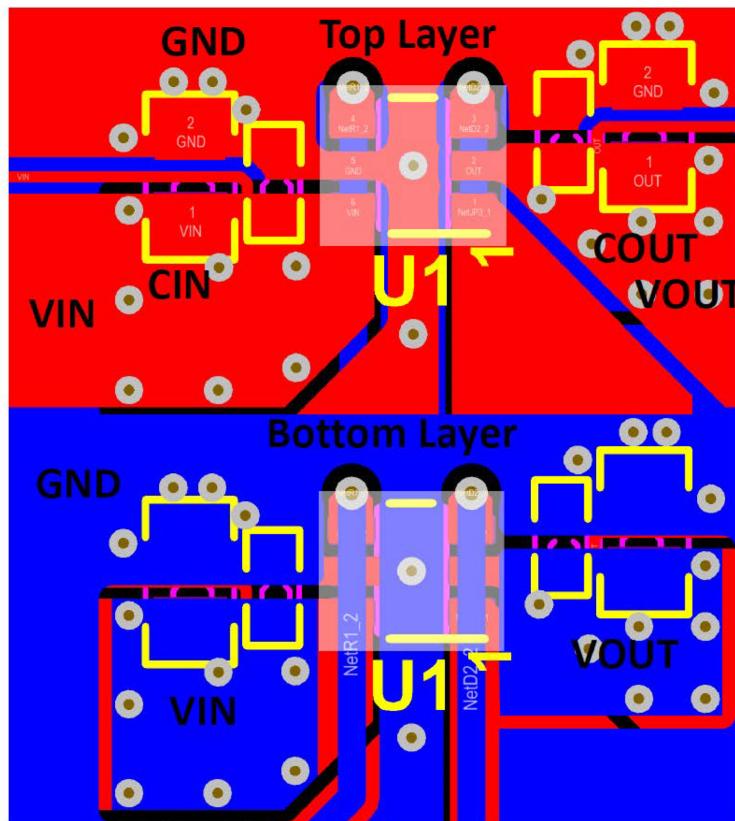

图 29. Board Layout

11.3 Thermal Considerations

The bq21040 is packaged in a thermally-enhanced MLP package. The package includes a thermal pad to provide an effective thermal contact between the IC and the printed circuit board (PCB). The power pad should be directly connected to the VSS terminal. The most common measure of package thermal performance is thermal impedance ($R_{\theta JA}$) measured (or modeled) from the chip junction to the air surrounding the package surface (ambient). The mathematical expression for ψ_{JT} is:

$$\psi_{JT} = (T_J - T) / P$$

where

- T_J = Chip junction temperature
 - P = Device power dissipation
 - T = Case temperature
- (7)

Factors that can influence the measurement and calculation of ψ_{JT} include:

1. Whether or not the device is board mounted
2. Trace size, composition, thickness, and geometry
3. Orientation of the device (horizontal or vertical)
4. Volume of the ambient air surrounding the device under test and airflow
5. Whether other surfaces are in close proximity to the device being tested

Due to the charge profile of Li-Ion and Li-Po batteries the maximum power dissipation is typically seen at the beginning of the charge cycle when the battery voltage is at its lowest. Typically after fast charge begins the pack voltage increases to $\pm 3.4V$ within the first 2 minutes. The thermal time constant of the assembly typically takes a few minutes to heat up so when doing maximum power dissipation calculations, 3.4V is a good minimum voltage to use. This is verified, with the system and a fully discharged battery, by plotting temperature on the bottom of the PCB under the IC (pad should have multiple vias), the charge current and the battery voltage as a function of time. The fast charge current will start to taper off if the part goes into thermal regulation.

The device power dissipation, P , is a function of the charge rate and the voltage drop across the internal PowerFET. It can be calculated from the following equation when a battery pack is being charged:

$$P = [V_{(IN)} - V_{(OUT)}] \times I_{(OUT)} + [V_{(OUT)} - V_{(BAT)}] \times I_{(BAT)} \quad (8)$$

The thermal loop feature reduces the charge current to limit excessive IC junction temperature. It is recommended that the design not run in thermal regulation for typical operating conditions (nominal input voltage and nominal ambient temperatures) and use the feature for non typical situations such as hot environments or higher than normal input source voltage. With that said, the IC will still perform as described, if the thermal loop is always active.

11.3.1 Leakage Current Effects on Battery Capacity

To determine how fast a leakage current on the battery will discharge the battery is an easy calculation. The time from full to discharge can be calculated by dividing the Amp-Hour Capacity of the battery by the leakage current. For a 0.75Ahr battery and a 10 μ A leakage current ($750 \text{ mAh} / 0.010 \text{ mA} = 75000 \text{ hours}$), it would take 75k hours or 8.8 years to discharge. In reality the self discharge of the cell would be much faster so the 10 μ A leakage would be considered negligible.

BQ21040DBVT.B	Active	Production	SOT-23 (DBV) 6	250 SMALL T&R	Yes	SN	Level-1-260C-UNLIM	0 to 125	130E

⁽¹⁾ **Status:** For more details on status, see our [product life cycle](#).

⁽²⁾ **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

⁽³⁾ **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

⁽⁴⁾ **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

⁽⁵⁾ **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

⁽⁶⁾ **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

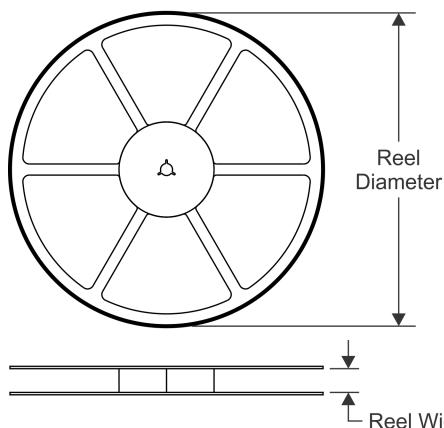

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.
